

# CPSC 216 - Positioning

We have looked at flex layout and grid layout.

Sometimes, being able to position elements by hand is also useful.

position: value ;

where value can be

- ① static
- ② relative
- ③ fixed
- ④ absolute

① static → this is the default positioning

② fixed →

position: fixed;

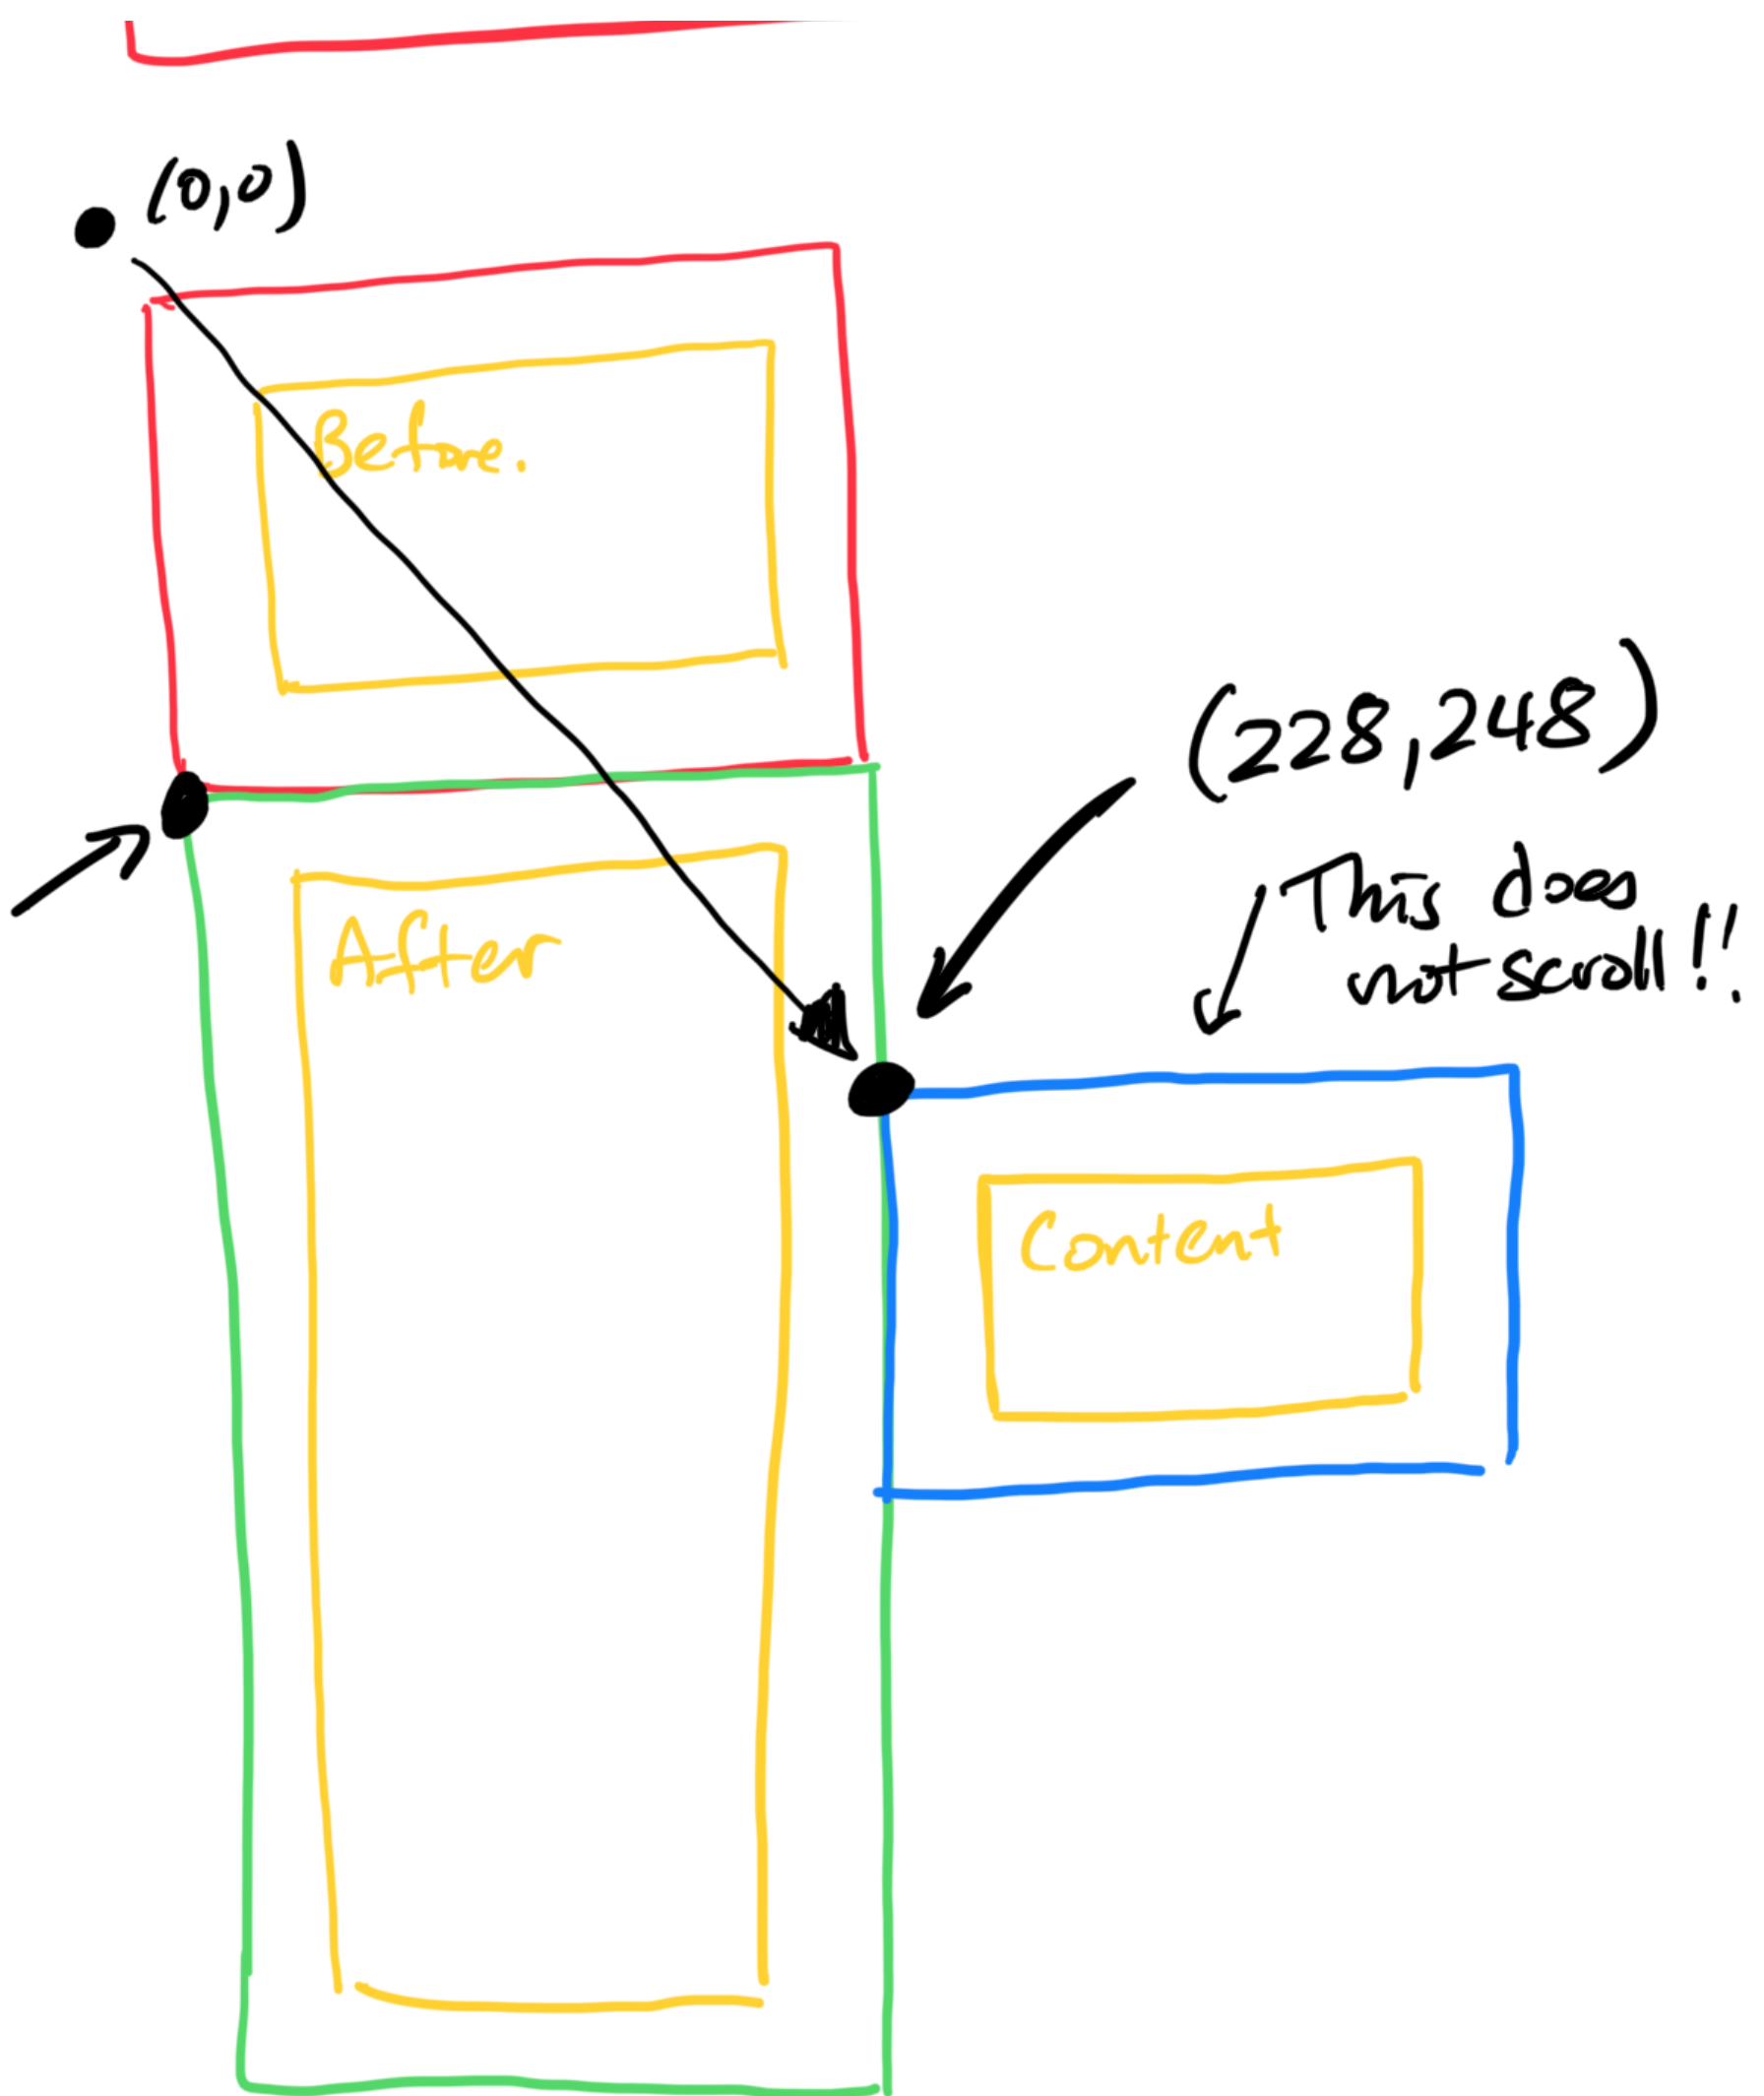

left: 228 px;

top: 248 px;

→ values are relative to the origin of the viewport  $(0,0)$

→ The fixed element is removed from the element flow, and is layered on top of the other elements.

→ fixed elements do not scroll with the document !!!

③ absolute → The element is placed according to the nearest ancestor element that uses . fixed, absolute, or relative positioning. If no such element exists, it is placed relative to the document body.

→ the element scrolls, unless the ancestor uses fixed positioning.

④ relative → position is relative to the element's default positioning !!

→ the element scrolls
